SUN COOKING
THE BEST PRACTICE IN INDONESIA

Herliyani Suharta

The Center for Energy Technology (BBTE) - BPPT PUSPIPETEK, Serpong, Tangerang 15314, Indonesia. E-mail: herli@iptek.net.id
Percentage of Households by Province and types of cooking fuel (electricity / LPG / kerosene and firewood). More than 90% of total houses in East Nusa Tenggara Province use firewood to fulfill their primary energy need.

In 1999, the total kerosene used by household was about **10.475 billion litters a year** (BPS, 2000: p282). The government made the scenario to raise the price of kerosene by 29 % per 1 January 2002 to dismiss subsidized of Rp.30.377.10^{12}.

This issue had blown the price of kerosene from Rp.495-Rp.650 per liter to Rp.800-1200 per liter in the last two weeks of the year 2001 until the second week of 2002. People should queue for hours to get kerosene. Some just cut fresh trees, chop it then dry it.

Decrease in subsidized for kerosene have driven the poor back to use fuelwood to fill their primary energy need for cooking.
Sun Cooking Program is a cheap tool to investigate problems in an effort to disseminate clean energy technology to a wider society.

It provides the path to penetrate deep into the root of the nation: the families.

Educational approach is expected facilitating the sustainable dissemination of knowledge of this new technology.

If we fully involve public in the process of science we shall not only give them understanding, we shall give the world a future.

Community Education

1600 local participants have been participated in these TT training's. They practice to make solar cooker and to witness the advantages of sun cooking. Also 100 foreign participants from 12 countries.

523 units have been disseminated.

A great number of government staffs were informed about the project and their possible contributions to tackle the future environmental problems related to people who desperately dependent on firewood.

Performance test of SOLAR COOKER TYPE HS5521 and TYPE HS5921 at Donggala, INDONESIA, August 11, 1999.

THE NEXT GENERATION WATCHING SUN COOKING.

Solar Cooker Type HS5521 at Trenggalek, East Java, Indonesia, March 1999.
Giving direction during cooking practice (left),
The villagers are practicing sun cooking (right)
Donggala, INDONESIA, August 1999.
PERFORMANCE TESTING

SOLAR COOKER
TYPE HS 7033,
Kerato village,
Sumbawa island,
Indonesia,
October 1998
Fig. 68  On 17 March 2003 the solar cooker HS5921 and HS6321 apply a thin aluminium net lined on the oven chamber surfaces, while on 12 March 2003 these cookers applied no aluminium net. The oven temperature of HS6321 is always higher that that of HS5921. On 17 March 2003, the oven temperature of HS6321 reached 177 C at 13:00.
Solar irradiation pattern on Perth (31.5 south latitude, 115 east longitude) in clear sunny day on 15 February 1999.
On 26 March 2003, the oven temperature profile of HS 6321 is lower than that of HS 5921, while on 17 March 2003 is higher. It is deduced that the high temperature reached on 17 March 2003 has damaged the silicon rubber sealant and reduced the heat tight quality.
The performance of six Solar Box Cookers Type HS6021 at tested without load on 14 April 2003.

SO coarse 1 reach 190°C at 12:30, SO 2 reach 191°C and SO coarse 3 reach 192°C.

The solar cooker with thin aluminium net (to create a coarse absorber surface) performs slightly better than that without net.

SO coarse 4 was exposed to the sun at 10:15, SO 5 at 10:45 and SO coarse 14 at 12:00.

On this day, SO 5 reached 180°C at 13:00.
Performance of six Solar Box Cookers Type HS6021 at test with and without load on 15 April 2003. SO5, SO13 and SOcoarse9 were tested without load.

SOcoarse1 for cooking: 1.1 kg tempe (10:35 - 11:50) & 1.75 kg rice in water plus nut (12:00 - end)
SO2 for cooking: 1.5 kg fishes (9:35 - 11:20) & 1.6 kg fishes (11:45 - 12:40) then empty
SOcoarse3 for cooking: 800gr fishes (9:40 - 11:00) and 2.1 kg corn cernel (12:00-end).
Fig. 2. The thermal network of solar box cooker type HS.

\[ Q_L = Q_{CD\text{wall}} + Q_{CD\text{bottom}} + (Q_{CV} + Q_R)_{\text{top cover}} \]

but \( Q_{CD\text{wall}} + Q_{CD\text{bottom}} \) is small and neglected. The energy losses \( (Q_L) \) between the nodes are the same, it is written in terms of heat resistance between the nodes at the absorber and at the bottom glass: \( Q_L = (T_{ov} - T_{bg})/R_{oven} \), or in terms of total heat resistance between the absorber and the ambient as: \( Q_L = (T_{ov} - T_a) / R_{total} = (U_L)_{av} (T_{ov} - T_a) \)

\[
\begin{align*}
R_{\text{wind}} &= 1/(h_{\text{wind}} + h_{R \text{tg-Ta}}) \\
R_{\text{top air}} &= 1/(h_{CV \text{mg-tg}} + h_{R \text{mg-tg}}) \\
R_{\text{bottom air}} &= 1/(h_{CV \text{bg-mg}} + h_{R \text{bg-mg}}) \\
R_{\text{oven}} &= 1/(h_{CV \text{p-bg}} + h_{R \text{p-bg}})
\end{align*}
\]

h is heat transfer coefficient, subscript CV represents convection, CD: conduction, R: infrared radiation, p: absorber plate. The written dimension is belonging to the cooker type HS 5521.

Spiral arrow is thermal flow. Straight arrow is solar radiation flow.
Fig. 3a. Time profile (versus time) of the solar box cooker type HS7033 tested without load on October 6, 1997 for SO5 only and on 7 October 1997 for SO5, SO1 and SO12 at Kerato village, Sumbawa regency, Sumbawa island, Indonesia.

Fig. 3b. The heat collection rate of three cookers: SO05, SO0, SO12. The bigger $\theta$ angle the better the performance in cooking. $T_{ovss}$ of SO5 is 199°C, SO1 is 184°C and SO12 is 169°C.
1. before steady state: data in the morning, 
2. quasi steady state: data around the noon and 
3. after steady state: data in the afternoon.

The morning data is shaping a linear trend line: \( T_{ov} = \vartheta (I) - \Omega \), which is then named as a heat collection rate. This line crosses the negative axis of temperature at \( \Omega \), which is named as dark ambient temperature. Slope \( \vartheta \) estimates the maximum temperature that might be reached by the cooker of different designs and estimates how low its dark ambient temperature. This line gives information on how a solar cooker of a certain design will perform if it is operated in different sites where the insolation is greater or smaller.

\( T_{ov} \) data around noon are gathering at the hook point. This temperature level is named as “Quasi Steady State Average (QSSAV) Level” that dictates the \( \vartheta \) angle of the HCR line. The afternoon data is shaping a polynomial curve.
The linear trend of heat collection rate of three solar box cookers type HS6021.

In order to get a heat collection rate some insolation data was deleted (see inset). The original solar insolation data can be seen in Fig. 70. At the solar insolation as high as 1100 Watt/m² these cookers might reach temperature of 220°C.
The thermal loss to the upper side per unit area:

\[ Q_L = (U_L)_{av} \cdot (T_{ov} - T_a) \]

The convection and infrared radiation loss factors are lumped in \((U_L)_{av}\).

The solar energy absorbed by the solar box cooker:

\[ S = (\tau \alpha)_{av} (I + I_R) = I (\tau \alpha)_{av} (1 + \rho_m \cdot f_R \cdot b) \]

I is the insolation on a horizontal surface (Watt/m²).

\(I_R\) is the reflected insolation by the mirror reflector.

\((\tau \alpha)_{av}\) is transmittance and absorptance product.

\(\rho_m\) is the reflectance of the mirror. \(f_R\) is the design factor.

\(b\) is the surrounding factor. For the solar box cooker without reflector: \(b = 0\).

At noon, the incident solar irradiation has no effect on the solar box cooker so that \(T_{ov}\) ripples about constant for a significant period.

**The possible reason is:** \(S = Q_L\)

At noon: \(\theta = 0\) leads to a lesser ground and beam reflection hit the mirror, therefore \(b = 0\), then we have:

\[
\frac{(\tau \alpha)_{av}}{(U_L)_{av}} = \left( \frac{T_{ov_{ss}} - T_{a_{ss}}}{I_{ss}} \right)
\]

The efficiency:

\[
\eta = \frac{Q_u}{A_o} I = (\tau \alpha)_{av} (1 + \rho_m f_R b)(U_L)_{av} (T_{ov} - T_a) / I
\]
Parabolic Cooker,
promoted by GTZ, Germany
during World Summit on
Sustainable Development.
Fig. 4* The performance of concentrator cooker K10 tested on 8 December 2003 at UPT LSDE, Serpong, Java. The cooker was start exposed to the sun at 11:05.

Load 1: 2 liters water in a black painted pan (having a hump at the center) was start loaded at 11:05. A space under the hump reduces $T_{\text{load}}$ sensitivity to follow the profilr of temperature at focus point

Load 2: 150 ml coconut oil in a flat frying pan (having shinny aluminium colour at the bottom) was start loaded at 13:03. When $T_{\text{load}} = 106^\circ\text{C}$ there are small bubbles come out from a shrimp crisp, which was frying. Temperature oil of $156^\circ\text{C}$ was not enough to fry a single shrimp crisp. Need to focus the reflector all the time or the temperature at focus decrease, see $T_{\text{load}}$ between 12:10 and 12:45.
For simple concentrator (non-imaging concentrator), the rate for solar energy input to the receiver is (see Donald Rapp, 1981):  
\[ Q_{\text{input}} = I C_e \eta_{\text{optical}} \]
I is the total insolation on horizontal surface in watt/m², \( C_e \) is the effective concentration ratio. \( \eta_{\text{optical}} \) is the overall optical efficiency, which is the product of \( \tau, \alpha \) and \( \rho \) for light interacting with all surfaces between the entrance aperture and receiver.

The efficiency is:
\[ \eta = \left[ I C_e \eta_{\text{optical}} - U (T_{\text{abs plate}} - T_{\text{amb}}) \right] / IC_e \]  \hspace{1cm} (1)

\( U \) is the heat transfer coefficient per unit area of the receiver. He assumed that for flat plate collector having a very good insulator, \( C_e = 1 \).

\[ \eta = \eta_{\text{optical}} - U (T_{\text{abs plate}} - T_{\text{amb}}) / I \]  \hspace{1cm} (2)

The solar box cooker type HS can be classified as non-imaging concentrator. Solar irradiation entering its aperture, its plane receiver distribute radiation onto all parts of the absorber. It has a good insulator. The efficiency is:
\[ \eta = (\tau \alpha)_{av} (1 + \rho_m f_R b) - (U_L)_{av}(T_{\text{ov}} - T_a) / I \]  \hspace{1cm} (3)

Eq. (2) = eq. (3) if:
\[ \eta_{\text{optical}} = (\tau \alpha)_{av} (1 + \rho_m f_R b). \]
But many scientists state \( \eta_{\text{optical}} = (\tau*\alpha) \), then we named the different as the effective concentration ratio:
\[ C_e = 1.01 (1 + \rho_m f_R b) \]
For a certain design, the value of $\tau$, $\alpha$, $\rho_m$ and $f_R$ are constant while the surrounding factor varies depending on the test site atmosphere. We did the simulation uses: - various $\rho_m$ : 0.96, 0.92, 0.88, 0.84 and 0.80; - $f_R$ values of different designs; - various optical efficiency ($\tau\alpha$) from 0.5 until 0.78; - various surrounding factor (b)

At certain $\tau$, $\alpha$, and $\rho_m$, increasing $f_R$ lowering the value of $b_{max}$. This means lower requirement for a higher value of surrounding factor, so that the choice to place the cooker increase. The design having a higher $f_R$ gives a better performance. The assessment of theoretical and experimental results shows that $f_R$ is vital as this parameter dictates the performance.
Degrading environment that support the living of the firewood consumers
Fig. 5 Poverty line in rural areas by provinces in Indonesia, in 1999.

The poverty line in East Nusa Tenggara is the lowest, that is Rp 66,143.- and 49.39% of population live below this poverty line, which means their incomes are below Rp. 66,143.-

Fig. 88. Percentage distribution of population by monthly expenditure per capita, in rural areas of various provinces in Indonesia, per 1999.

Only 4 expenditure classes until Rp. 99,999.- are shown.

In East Nusa Tenggara, 32.98% of the villagers spend Rp. 40,000-Rp. 59,000 in a month.
The socio economic survey in 1999 (BPS, 2000: p.504) shows:

The average of monthly expenditure per capita in rural areas was Rp. 109,523. 62.9% was spent for food.
The poverty stays and becomes chronic as they have only 38.1% for non-food.

The lowest was in East Nusa Tenggara in the range Rp.40,000 - Rp.59,999 (US$ 3.4 – US$ 7.4)
The firewood consumers never feel the meaning of fossil fuel subsidize.

Degraded environment make the rural women to work harder. Inability to overcome social situation such as gender discrimination add their burden, less food, poor health and inability to provide a better education to their children. This poverty is inherited to their malnourished baby.

The children grow then life in similar levels of education, similar well-being and similar jobs as their parent.
Seems difficult to alleviate this poverty cycle.

However, the participants in the training "technology transfer of solar oven" do not lose their spirit to learn.

In this minimum standard of living, they have proved their strong willing to improve their situation positively.

A little transport money as an appreciation for their good spirit in learning is meaningful to reduce their burden.
If the number of low-income peoples is dominant, sustainable development becomes a difficult choice to be taken. The pressures to improve standard of living push people to exploit the natural resources. THEN............
The critical lands by provinces and the rehabilitation program to reduce critical lands of Indonesia in the 5-years development period: 1999 - 2003 (PELITA VII)

Critical lands in Kalimantan is 7.179 million hectares in total.

Fig. 7 Forest area in each province based on agreed forest land use, per March 1998. 
Convertible production forest in Irian Jaya is 11775000 hectares. 
Getting funding flows to these destitute peoples is very tough. These peoples have a low level of education, have no network as a guarantee therefore they need a concealing.

However, the concealing mechanism should be designed in effective way to drive a greater percentage of funding flows to the poor.

Volunteering system might improve this. It is a need to bring every finding into the attention of international policy makers in order to break the funding scarcity in helping the poor live in barren areas of the world.
The involvement of the government is urgent. Create a huge program for solar cooker dissemination, as the choices are:

* to revamp the policy framework to be easily work in practice and to allocate a partial funding of support,

or

* the environment will be depredated severely lead to a more chronic poverty in the country.

3. Positioning

**VALUE EXECUTED**
1. Brand as indicator
2. Service to aim change

**TACTIC APPLIED**
1. Tactic derivation
2. Marketing Mix
3. Selling
BE AWARE

SLOW ACCEPTANCE IS NOT A FAILURE, so encourage all the existing efforts of change. Whatever amount of progress is a good achievement.

IF GOOD ACTION IS EFFORTED AS CHILDREN WATCH THE PARENT USING SOLAR COOKER. They will grow up and might be the good seeds for a new vision.

Therefore we must enthusiastically push every effort, plea the effort, give courage to raise optimism in delaying the growing environmental problems: GLOBAL WARMING AND CLIMATE CHANGE.
In the longer term, greater understanding might arise from multiple sites and could help to shape a fundamental framing of policy problems.

The field research findings into the broader impacts within the policy elite might help shift the policy debates in providing facilities and funding for this type of community education in gender equity basis.
No technology will spread by itself

It needs: - Your thought, - Your hand, - Your help - Your support

The future of our country is in your hands

Effort in Renewable Energy dissemination involves:
- Central Government Initiatives
- Local Government Initiatives

Plate Carree projection: equidistant along Equator and along meridians; not equal area; not conformal (deformation of shape towards the poles).

About December 22 at 12.00 U.T.C.
Daylight: north of Arctic Circle; 24 h.
London (51°30' N): 8 h.
At the Equator 12 h.

About June 21 at 12.00 U.T.C.
Daylight: north of Arctic Circle; 24 h.
London (51°30' N): 17 h.
At the Equator 12 h.

Direction of Earth's rotation. The Earth rotates on its axis from west to east and completes one rotation in about 24 hours. The Earth has been divided into 24 Standard Time Zones. The lines separating these Zones on land mostly follow country or province boundaries. Many countries however use a different standard, e.g. British Summer Time.
ENVIRONMENTAL IMPACT

1. Energy harnesses from the sun

Each cooker can give $2-3 \text{ KW}_{\text{thermal}}$ in a day
(6 hours from 9:00 to 15:00)

Assume that the cooker is used only 146 days a year (40%), 500 cookers will provide thermal energy as much as

$$(500 \times 3 \times 146 \times 6 \times 3600 =)$$

4730 Giga Joules/second in a year.

This equal to $1.314 \text{ GWh}_e$
ENVIROMENTAL IMPACT (continu)

2. Carbon credit

- A coal fired power plant might produce 1000 tonnes CO$_2$/ GWh$_e$.

If we compare this to the energy harnesses from 500 solar box cookers, these cookers will have saved pollution of 1314 tonnes CO$_2$ eq. / year.

- Assume that the abatement cost is 10 US$ per ton CO$_2$ eq. , the use of 500 solar cooker will collect yearly carbon credit of 13140 US$.

This equals to the prize of 438 solar cookers (if the cooker price is about 30 US$).
3. Re-forestation impact

- The use of 500 cookers is assumed will archive 40% fuelwood used by 500 families which is equal to 27000 kg wood / month (each families uses 135-180 kg wood / month).

  This wood saving is equal to save 42 trees of 4-years old from cutting per month or 500 trees per year.

- The use of solar cooker contributes aforestation in barren area and give an additional facilities for terrestrial carbon sink. This aforestation cost is assumed equal to the price of 218 cookers.

- Community education approach to make 500 cookers involving 1000 participants. This approach is rated as benefit in the form of:
  - Local abilities in making another 500 cookers in the future.
  - Raise the awareness of the locals on gender equity, health issues and on the environmental issues: DEFORESTATION, GLOBAL WARMING AND CLIMATE CHANGE. These impacts are rated as the price of 750 cookers.
ENVIRONMENTAL IMPACT (continu)

5. Value of SUN COOKING program via community education

This SUN COOKING program will have the multiplication factor of 

\[ \frac{(438+218+500+750)}{500} = 3.8 \]

or equal to

\[ (3.8 \times 500 \times 30 \$) = \text{US}\$ 57000 \]

This offer a good reason to finance Sun Cooking Program in barren area where wood is limited, especially if the CO\textsubscript{2} mitigation cost will not going cheaper as the concentration of CO\textsubscript{2} in the atmosphere raise steeply while the world’s carbon sink quality degraded.

When people become use to sun cooking and no need to do a community education then pure business can be run
